Flow Rate: volume of liquid the moves through a microchannel in a specific amount of time (mL/min)
- driven by a precise instrument like a syringe pump (delivers exact fluid volumes over a set amount of time)

↳ experimentally determine flow rate that gives most clearest separation
- once flow rate is picked, then calculate Reynolds # (Re) and Dean # (De)

↳ $Re = \frac{\rho U D_h}{\mu}$ ↳ $De = Re\sqrt{\frac{D_h}{2R}}$

radius of curvature ↗ (centerline curvature)

↳ Inner centerline radius: 10 mm Pitch: 2.2 mm
↳ start and then experimentally determine

10 mm straight section before inlet causes a lot of overlap with spirals, do 2mm instead.
↳ should be sufficient
